# **Materials Science 1: Physical Foundations of Materials**

## **Materials Science 1: Physical Foundations of Materials**

### **Summary**

This paper introduces the physical foundations underpinning important areas of Materials Science. You will learn some basic concepts of atomic arrangements in perfect crystals and how we can use diffraction of X-ray and electron waves to measure these arrangements. The use of waves will also be used to explore basic concepts in wave mechanics and quantum theory, and how these theories can be used to explore the behaviour of electrons in materials and how bonding occurs. Quantum theory involves randomness and probability, and these ideas are continued in the study of random processes in materials to explain phenomena such as diffusion and the behaviour of gases. The physical principles of electricity and magnetism are introduced and used to explore the electrical and magnetic properties that are so important for many applications of materials.

Physical Foundations of Materials comprises:

- The Study of Crystalline materials by Diffraction (8 lectures)
- Electromagnetic Properties and Devices (12 lectures)
- Random Process and Statistical Physics (8 lectures)
- Wave mechanics, Quantum Theory and Bonding (12 lectures)

## **The Study of Crystalline Materials by Diffraction**

### **Overview**

The vast majority of materials are crystalline, and so any study of materials must start with introducing some basics of crystallography including the use of a unit cell to describe the periodicity in the crystal and how to represent symmetry in crystals. In a crystal, the atoms form a periodic lattice that can act as a diffraction grating to radiation, and diffraction is therefore an important characterisation tool. The use of diffraction as a practical tool for identifying crystal structures in materials will be introduced.

### **Lecture Content**

#### **Lecture 1. The Periodic lattice**

- Definitions of a lattice, mesh, unit mesh and motif
- The Unit Cell and basis vectors
- The structure of metals and some binary compounds

#### **Lecture 2. Symmetry in 2D**

- Symmetry elements in 2D
- Lattice symmetry in 2D
- The 2D plane point groups

#### **Lecture 3. Crystallographic planes and directions**

- Miller and Miller Bravais indices describing planes and directions
- Calculation of interplanar spacings, angles between planes and directions

#### **Lecture 4. Waves**

- Wave particle duality for X-Rays, electrons and neutrons
- Mathematical representation of harmonic travelling waves
- Interference of waves and the principle of superposition

## Lecture 5. Diffraction in 2D and 3D

Diffraction from a 2D grating, the effects of slit width, separation and grating size  
Diffraction from a 3D lattice; The Laue equation  
Braggs law

## Lecture 6. Scattering by atoms

Scattering factors for electrons, X-rays and neutrons  
Structure factors  
Forbidden reflections in cubic systems

## Lecture 7. The reciprocal lattice

Constructing the reciprocal lattice  
The Ewald sphere construction for single crystal and powder diffraction  
Observing the reciprocal lattice with electron diffraction

## Lecture 8.

Practical X-ray, electron and neutron diffraction experiments  
Indexing powder x-ray and electron diffraction patterns  
Example phase identification using powder diffraction

## Electromagnetic Properties and Devices

### Overview

Next generation batteries for electric vehicles; sustainable materials for touch screen displays; faster, more compact and efficient computing; futuristic cloaking devices: these are just a few examples of the wide range of technological applications which exploit electromagnetic phenomena in materials. This course introduces the physics of classical electromagnetism and how different kinds of material respond to electrical and magnetic fields. We will explore how the structure of a material influences its electromagnetic properties including the origins of phenomena such as ferroelectricity and piezoelectricity, and how the coupling between electric/magnetic/strain fields can be exploited in real devices.

### Part I: Electrical properties of materials

#### Theory of electrostatics

- Basic concepts of charge, force on a charge, potential and electric field, capacitance
- Calculations using superposition principle and Gauss' theorem in examples with simple geometries

#### Dielectric materials

- Concepts of polarisation, dielectric permittivity, susceptibility, and electric displacement (D).
- Calculations involving simple geometries of capacitor.
- Example devices

#### Piezoelectric, pyroelectric and ferroelectric materials

- Concept of coupling between fields (e.g. electrical and strain)
- Crystal symmetry requirements
- Examples of materials
- Applications (e.g. Atomic Force Microscope, ferroelectric RAM)

## Electrical transport

- Basic concepts of current, current density, resistance, Ohm's law.
- Electrical conductivity of metals – Drude model
- DC circuits

## **Part II: Magnetic properties of materials**

### Theory of magnetostatics

- Concepts of magnetic field, flux and induction.
- Calculations of magnetic field from currents in simple geometries using Biot-Savart and Ampere's laws (e.g. straight wire, loop, solenoid, toroid)
- Lorentz force on charges moving in electric fields

### Electromagnetic induction

- Faraday's law and Lenz's law
- Concepts of self and mutual inductance

### Magnetic materials

- Concepts of magnetisation, magnetic susceptibility, magnetic permeability and magnetic intensity (H)
- Introduction to paramagnetic, diamagnetic and ferromagnetic materials
- Applications of ferromagnets (saturation magnetisation, hysteresis loops, remanent field, coercivity, hard and soft ferromagnets)
- Example magnetic devices

## **Part III: Electromagnetic waves**

### General theory of electromagnetism

- Maxwell's equations in integral form
- Concept of displacement current

### Electromagnetic waves

- General wave equation
- Formulation in integral form

### Interaction of materials with EM waves

- Refractive index
- Conductors
- Example applications

Library 21 BLE/a or 21 BLE/b. <http://solo.bodleian.ox.ac.uk/permalink/f/n28kah/oxfaleph010253559> More advanced text - rather old fashioned.

Duffin, W. J. **Electricity and Magnetism**. 4th ed.], New impression. edition, W. J. Duffin, 2001. <http://solo.bodleian.ox.ac.uk/permalink/f/n28kah/oxfaleph015239530> Good basic text with similar level of mathematical complexity as lecture course.

Feynman, Richard P. et al. **The Feynman Lectures on Physics**. Addison-Wesley, 1963. Materials Dept. Library 20 FEY/Bb or 20 FEY/Cc or 20 FEY/Ac.

<http://solo.bodleian.ox.ac.uk/permalink/f/n28kah/oxfaleph010079911> Vol II, Ch. 1-22 are worth reading. The mathematical formalism is more complex, but is clearly explained in the text.

Vol. 1, Ch. 2 gives an interesting historical overview of “Basic Physics” which helps set the classical physics discussed in this course in context.

Solymar, L. and D. Walsh. **Electrical Properties of Materials**. 6th edition, Oxford University Press, 1998. Materials Dept. Library 21 SOL/Q.

<http://solo.bodleian.ox.ac.uk/permalink/f/n28kah/oxfaleph013048023> More advanced text - interesting examples. “Basic Physics” which helps set the classical physics discussed in this course in context.

## **Random Processes and Statistical Physics**

### **Overview**

Quantum theory shows us that probability plays an important role in the processes that control materials properties. This course explores that idea in more detail, looking at how randomness can control structure, how it plays a role in diffusion processes and in the interaction of gases with surfaces. The statistical concepts introduced can be used to explain classical thermodynamics, and the statistical nature of heat capacity is introduced.

### **Lecture Content**

#### **Random processes in materials**

- Examples of random processes e.g. diffusion
- Random walks – applications (e.g. polymers)

#### **Rapid random motion of gas molecules**

- Basic assumptions of kinetic theory
- Simple derivations of pressure and temperature
- Ideal gas equations

#### **Statistical distributions of molecular motions**

- Statistical notation
- Collision with walls – relating pressure to collision rate
- Deposition of materials and thin film growth
- Effusion

#### **Pressure and distribution of velocities**

- Derivation of pressure as statistical average and need for mean-square velocity
- Maxwell-Boltzmann distribution of velocities

## **Collisions and transport**

Concept of mean free path

Rate of collisions in gases and relation to reaction kinetics (effect of temperature and pressure)

Rate laws. Determination of reaction order and rate constants/The Arrhenius equation.

Transport in materials – diffusion, heat flow and viscosity

Effect of temperature and pressure on transport

## **Non-ideal gas behaviour**

Interaction between molecules

Modification to ideal gas law

## **Equipartition theory (links to thermodynamics course)**

Heat capacity of gases

## **Breakdown of classical physics**

Heat capacity of solids

## **Wave Mechanics, Quantum Theory and Bonding**

### **Overview**

Many properties of materials are controlled by how electrons behave in them. Because of wave-particle duality, we need to consider electrons as waves. This course shows how these ideas lead onto quantum theory and the idea of discrete states. We can then think about what happens over different length scales including atoms and nanomaterials. The concept of bonding and molecular orbitals is introduced before thinking about entire crystals and how bands are formed.

### **Lecture Content**

#### **Wave particle duality**

Evidence, electron diffraction, photoelectric effect, atomic spectra

DeBroglie wavelength

Interpretation of quantum mechanical wave

#### **Observation of quantum systems**

Perturbation of observed systems

Postulates of quantum mechanics

Operators and commutators

Uncertainty principles – momentum-space / energy-time

#### **Waves and the wave equation**

Wave packets

Dispersion, phase velocity and group velocity for electrons and photons

Schrödinger equation

#### **Waves on a string, standing waves and boundary conditions**

Mathematical notations for waves

Free and fixed boundaries

Nodes and antinodes

Harmonics

Wave equations

### **Infinite potential well**

Infinite potential well

Waves in a 1D box, quantisation, quantum confinement

Illustrated with energy levels in nanomaterials (QDs etc.)

### **Measurement in quantum mechanics**

Decomposition into eigenstates

Statistical nature of measurements and expectation values

Wavefunction collapse and Schrödinger's cat

### **Transmission and reflection of waves**

Finite boundary potentials

Boundary condition matching

Transmission and reflection coefficients

Tunnelling and evanescent waves

### **Extension to 3D**

Separation of variables

Angular momentum

Quantum numbers  $n$  and  $l$

### **The hydrogen atom**

One electron atoms

Heavier atoms

### **Spin**

Fermions and bosons

Pauli exclusion principle

Filling of atoms

### **Multiple finite wells**

Molecular orbital theory – bonding and antibonding

The concept of the broadening of discrete states into bands

The concept of a crystal momentum to describe a wave

## **Materials Science 2: Structure and Mechanical Properties of Materials**

## **Materials Science 2: Structure and Mechanical Properties of Materials**

### **Summary**

This paper introduces the basic structures of materials –both crystalline and amorphous and how they deform and fail under applied stresses. You will learn the theory behind methods used to study the atomic arrangement in perfect crystals and in then apply these to the common lattice defects which can occur. How these defects control the mechanical properties of the materials will be introduced in both single crystal and more engineering relevant material systems. This will cover elastic properties, including stress and strain analysis, yield phenomenon, post yield plastic flow and linear elastic fracture mechanics.

Structure and Mechanical Properties of Materials comprises:

- Elastic Deformation (8 lectures)
- Structures of Crystalline and Glassy Materials (12 lectures)
- Defects in Crystals (8 lectures)
- Mechanical Properties (12 lectures)

## Elastic Deformation

### Overview

This course introduces the basics of stress and strain. Analysis of simple bending conditions (cantilever, three point, four point) as required for mechanical testing analysis are developed, including shear force and bending moment diagrams. Mohr's circle is introduced as a graphical method to calculate stress or strain states at any point in a plane for arbitrary loading conditions. The underlying physics of elastic constants and how they relate stress and strain will be derived. Time dependant elastic deformation (viscoelasticity) will be introduced through examples in polymeric materials. Stress states and the elastic deformation of thin wall pressure vessels and torsional deformation of prismatic rods will be discussed.

### Lecture Content

#### Equilibrium

- Resolving forces

- Taking moments

#### Internal forces

- Shear force and bending moment diagrams

#### Stress

- Definitions, normal stress, shear stress, notation

- Transformation of axes

- Resolving stress onto an inclined plane

- Mohr's circle for stress

- Principal stresses, maximum shear stress

#### Strain

- Definitions, normal strains, shear strain

- Engineering and tensor strains

Transformation of axes  
Mohr's circle for strain  
Principal strains, maximum shear strain

### **Elasticity and interatomic forces**

Recap of fundamentals  
Physical basis for Hooke's law

### **Hooke's law**

Relating stress and strain  
Young's Modulus  
Shear modulus, bulk modulus  
Poisson's ratio

### **Viscoelastic deformation**

Simple spring and dash pot models

### **Elastic deformation examples**

Thin wall pressure vessels  
Bending of beams  
Torsional deformation

## **Structures of Crystalline and Glassy Materials**

### **Overview**

This course will investigate why different classes of materials exist and how different forms of interatomic bonds lead to different materials properties. Ways to represent and describe bonding will be introduced through the use of example materials with common crystal structures. Key classes of materials (ceramics, metals, polymers, glasses) will be introduced and specific applications of these materials used to illustrate key points.

### **Lecture Content**

#### **Types of Bonding**

Examples of simple crystal structures

Close packing of spheres. FCC and HCP and stacking sequences

Octahedral and tetrahedral interstices in close-packed structures

Basic Concepts

- Definition of metals, ceramics, polymers, glasses and semiconductors
- Types of bonding: ionic, covalent, metallic, van der Waals
- Dependence of interatomic forces on distance
- Non-directional bonds: van der Waals, metallic; close packing
- Directional bonds: the covalent bond, hybrids
- Electronegativity, ionic bonding, co-ordination
- Trends in the periodic table

#### **Stereographic projections and the Weiss zone law**

Pole figures

Stereographic projection. Properties of projection

Great circles, Small circles, Zones

Preservation of angular truth

Wulff net

Zone axes, Zone symbols

Weiss zone law

Crystallographic calculations

Addition rule, Use in plotting stereogram

Use to illustrate coordination, e.g. for tetrahedral structures, and symmetry directions in common lattice, e.g. cubic

Examples from real structures ( e.g. zinc blende, wurtzite, NiAs)

## **Ceramic materials bonding**

Ionic Structures

- Structures of composition AX (CsCl, NaCl, ZnS)
- Principles of ionic bonding: radius ratio criterion, energy considerations, Madelung constant
- Structures of composition AX<sub>2</sub>
- Pauling's Rules

Covalent Structures

- Simple covalent structures (diamond, graphite)
- Molecular crystals
- Structures of some ceramics.

Perovskite structures

- Basic properties

## **Glasses and amorphous materials**

Idea of local ordering

SiO<sub>2</sub> coordination

Network formers

Basic properties of glasses

## **Bonding and structure of polymers, molecular crystals, polymorphism**

Mixtures of bonding. T<sub>g</sub>. Random walk model

Thermosetting vs thermoplastics v rubbers

- Rubber, polyethene, nylon6-6

Polymer properties

- Degree of polymerisation
- Molecular weight distribution
- Stereoregularity

Glass transitions

## Metals, solid solutions and ordered alloys

Trends across the Periodic Table

Typical metallic structures (FCC, BCC, HCP); atomic packing factor, unit cell volume, theoretical density

Relationship between structure, bonding and properties of pure metals

Interstitial and substitutional alloys – iron-carbon, iron-chromium, aluminium-copper

Hume-Rothery Rules: size factor, electrochemical factor & relative valency factor

Electron compounds; normal valency compounds; size factor compounds - interstitial compounds

## Defects in Crystals

### Overview

This course will introduce the basic forms of defects present in crystalline materials. Their effect on physical properties will be considered. Diffusion of point defects and implications for systems such as ionic conductors will be covered. Dislocations will be given the fullest consideration. Differences between edge and screw dislocations. How dislocation move and control the mechanical properties in single crystal metals will be covered. Methods for imaging dislocations and calculating their nature will be introduced. This course will build on the diffraction and crystal structures courses and also use elasticity analysis introduced in elasticity and structures. It will lead into the mechanical properties course.

### Lecture Content

#### Introduction

Types of lattice defects (point, line, planar)

What do defects control – e.g. (doping of semiconductors, strengthening in metals)

#### Introduction to dislocations

How do we know they exist?

Structure of edge and screw dislocations in simple cubic materials

Definition of the Burgers vector

#### Imaging dislocations

Microscopy and diffraction techniques

Introduction to diffraction contrast TEM imaging and  $\mathbf{g}\cdot\mathbf{b}$  analysis

Etch pits methods

#### Dislocations in cubic lattices

Self-energy of a dislocation

Slip systems

Partial dislocations and stacking faults

Peach Koehler formula for force on dislocation  
Motion of dislocations under an applied stress  
Dislocation sources

### **Point defects and diffusion**

Point defect types  
Concentration of point defects  
Vacancy motion and solid state diffusion  
Diffusion mechanisms and Fick's first and second laws

### **Planar defects**

Planar defect types  
Stacking faults  
Twinning  
Structure of grain boundaries and concepts of grain boundary energy  
Interphase and antiphase boundaries

### **Background reading**

Chapter 6

## Mechanical Properties

### Overview

This course builds on the elastic behaviour course looking at how materials behave beyond the yield point and from the defects course, looking at how defects can control mechanical behaviour. The basic methods of materials testing will be introduced, this will link into several practical classes. Plastic behaviour will be covered both at the micro and macroscale. At the microscale building on the defects course, but concentrating on the strength of polycrystalline metals and introduce the concept of strengthening through precipitates, using aerospace aluminium alloys as examples. This will be followed by a macroscopic treatment of yield through Tresca, Von Mises and Coulombs Yield Criterion for deformation in bulk metals and polymers. Fracture will be covered in ceramics and glasses using a linear elastic treatment. Toughening mechanisms will be introduced including fibre toughening which will lead to a first treatment of composite materials. Finally optimisation of materials properties will be covered, looking at a range of properties including design for strength, stiffness and cost.

### Lecture Content

#### Testing mechanical properties

Why we test, how we test, what we test.

Types of stress and strain

Introduction to stress- strain curves for metals, ceramics, polymers

#### Microscale mechanisms of plasticity and how we control plastic strength

Metals – chemistry and crystallographic effects

Metals –grain size; Hall-Petch effect, how to control grain size

Work hardening in metals. Single vs double slip. Effect of crystal structure and stacking fault energy on work hardening behaviour

Twinning deformation, difference to annealing twins  
Plasticity in polymers, glass transitions temperatures

### **Predicting plastic failure at bulk or component length scales**

Tresca and Von Mises yield criterion – metals  
Coulomb yield criterion – polymers  
Using yield criterion for combined tension-torsion loading

### **Fracture processes**

Recap of theoretical strength  
Stress concentrations at small flaws  
Griffith theory  
Orowan Modification  
Ductile to brittle transitions in metals  
Fracture and failure in polymers  
Toughening mechanisms –transformation toughening, microcracking, composites

### **Introduction to mechanics of composites**

Design of composites – examples from aerospace and F1  
Rules of mixture in long fibre composites

### **Optimising materials selection**

## **Materials Science 3: Transforming Materials**

## **Materials Science 3: Transforming Materials**

### **Summary**

This paper introduces you to how the microstructure of materials can be transformed and controlled through processing, in order to control and optimise the properties that are required for the material to perform its function. The theory of thermodynamics is critical to all transformations in materials, and you will be introduced to the first and second laws of thermodynamics and their role in phase diagrams. This will be developed further in Microstructure and Processing of Materials I & II, which will describe how phase transformations can be used to control microstructure, with case studies in metallic, ceramic and polymeric systems. Electrochemical processes, which are driven by thermodynamics, are important in the production and degradation of materials, as well as the performance of materials for energy storage. The developing field of nanomaterials will then be introduced, with emphasis on nanomaterial synthesis, properties and applications.

Transforming Materials comprises:

- Thermodynamics (8 lectures)
- Introduction to Nanomaterials (8 lectures)
- Microstructure and Processing of Materials I (8 lectures)
- Electrochemistry (8 Lectures)
- Microstructure and Processing of Materials II (8 lectures)

## Thermodynamics

### Overview

Thermodynamics is fundamental to the physical and chemical processes that occur in materials. This course underpins many subsequent parts of the materials degree. It focuses on the first and second laws of thermodynamic, using practical examples, and leads to an understanding of phase stability.

### Lecture Content

#### First law of thermodynamics

Thermodynamic Definitions: work, heat, internal energy, state and path functions

Simple gas expansion

Reversible and irreversible processes

#### Enthalpy and heat capacity

Heat capacity at constant volume

Storage of internal energy

Constant pressure processes

Heat capacity at constant pressure

Enthalpy variation with temperature

Hess's law. Kirchhoff's equation

#### Entropy and the second law of thermodynamics

Definition of a spontaneous process

Entropy variation with temperature

Entropy of phase changes

Definition of the Gibbs function

Thermodynamic Master Equations

Gibbs function variation with temperature and pressure

Gibbs Helmholtz equation

Statistical mechanics definition of entropy

## **Mixtures and equilibria.**

Dealing with mixtures  
Chemical Potential  
The Van't Hoff isochore

## **Applications of thermodynamics to metallurgy**

Ellingham diagrams  
Stability of oxides  
Thermodynamics of the Blast Furnace  
Extraction of metals from Sulphides  
Predominance diagrams

## **Phase changes.**

The phase rule and phase diagrams  
The Clausius-Clapeyron equation  
Vapour pressure. Ideal solutions  
Non-ideal solutions  
Free energy of mixing  
Regular solutions  
The quasi chemical model

## Introduction to Nanomaterials

### Overview

This course serves as an introduction to the rapidly developing area of Nanomaterials, beginning with the peculiar characteristics of materials at the nanoscale and the new technologies they enable. Important methodologies for nanomaterial synthesis are described, and the structures of key nanomaterials are introduced, including carbon nanomaterials and chalcogenides. The upscaling of the manufacture of nanomaterials is considered, together with associated ethical and safety issues. The course concludes with current and potential applications of nanomaterials in medicine and energy.

### Lecture Content

#### Introduction

Nanoscale,  
Nanotechnology,  
Surface areas per unit volume,  
0-D, 1-D, 2-D materials

#### Synthesis of nanomaterials

Chemistry of particle synthesis,  
Sol-gel processing,  
Core-shell nanoparticles,  
Composites, coatings, thin films,  
Chemical vapour deposition, arc discharge, exfoliation

#### Carbon nanomaterials

Fullerenes, nanotubes, graphene

#### Other nanomaterials

Chalcogenides, other 2-deg materials

## **Manufacturing**

Upscaling,  
Safety of nanomaterials,  
Ethics and regulation

## **Physical properties of nanomaterials**

Introduction to electrical, optical and mechanical properties at the nanoscale

## **Applications of nanomaterials**

Medical applications,  
Energy materials

## **Background reading**

## Microstructure and Processing of Materials I

### Overview

Material microstructures are the product of phase transformations that occur during processing, so an understanding of what controls phase transformations is important in all material systems. This course builds on the thermodynamics course to explain how we determine phase diagrams, and how they predict which equilibrium phases are formed by what reactions. This will be illustrated with examples of reading phase diagrams to predict how to process a range of materials by both liquid-solid and solid-solid transformations.

### Lecture Content

- Concepts of microstructure
- Terminology for microstructures
- Gibbs phase rule
- Solutions, compounds and mixtures
- Simple phase diagrams; tie lines and invariant points
- Ideal and regular solution models
- Tangent and lever rules

### Phase diagrams

- Derivation from free energy-composition curves
- Continuous solutions, immiscibility and ordering
- Eutectic, peritectic, eutectoid peritectoid and monotectic reactions. Intermediate phases

### Using phase diagrams

- Solidification: driving force for solidification; introduction to homogeneous and heterogeneous nucleation

- Solidification of solutions: partition coefficient; Scheil equation and segregation; cells and dendrites, cored microstructures
- Eutectic and peritectic transformations and microstructures
- Solid state phase transformations
- Introduction to precipitation, homogeneous and heterogeneous nucleation, equilibrium precipitation and age hardening
- Heat treatments
- Introduction to recrystallization and grain growth

## Electrochemistry

### Overview

Electrochemistry is fundamental to the extraction of metals by electrolysis and also their corrosion and protection from degradation. The same processes of electrochemical thermodynamics are critical to the design and performance of materials for electrochemical energy storage, and sensors that rely on electrochemical processes. This course provides an introduction to applications of electrochemistry, and considers the thermodynamics of electrochemical processes. Factors that influence the kinetics of electrochemical reactions, including transport properties and interfaces are considered, using case studies.

### Lecture Content

#### Introduction to electrochemistry

Overview: electrodes, electrolytes and interfaces

Applications:

- Electrolysis
- Electrodeposition and electroplating
- Electro-mining
- Electroanalysis and sensors
- Corrosion and protection
- Energy conversion, production and storage

#### Electrochemical thermodynamics

The physics of phase potentials

Cell potential and Gibbs free energy

Electrochemical potential

Half-reactions and standard reduction potentials

Cell potential and concentrations: Nernst equation

Reference electrodes

Pourbaix Diagrams

Case studies: sensors (potentiometry), maximum theoretical specific energy in batteries

### **Electrolytes and transport properties**

Electroneutrality

Non-ideal behaviour of electrolyte solutions: activity coefficient

Transport properties: conduction, diffusion, migration

Case studies: activity coefficient, diffusion coefficient and transference number

### **The electrode-electrolyte interface: the electrical double layer**

Structure of the electrical double layer

Case study: supercapacitors

### **Kinetics of electrode reactions**

Charge transfer across the interface

Overpotential

Butler-Volmer model and the Tafel equation  $\left[ \frac{E}{SEP} \right]$

Case study: electrocatalysis

## Microstructure and Processing of Materials II

### Overview

These lectures build on the preceding course, using case studies in metallic (solidification and heat treatment), polymeric and ceramic systems, to develop an understanding of how the microstructures of materials can be controlled through processing.

### Lecture Content

#### Casting and Al-Si

- Ingot solidification and cooling curves
- Structures of cast metal, faceting, Na modification
- Engineering applications

#### The Fe-C system

- Eutectic reaction and cast irons
- Eutectoid decomposition
- Hypo and hyper eutectoid alloys
- Martensite and bainite
- TTT curves. Typical microstructures for different heat treatments
- Engineering applications

#### Polymers:

- Polymer blends and crystallisation
- Manufacturing techniques
- Engineering applications

#### Ceramics:

- Powder processing
- Sintering
- Ceramic microstructures
- Engineering applications

## **Mathematics for Material Science**

## Mathematics for Material Science

### Summary

Mathematics is the language of the physical sciences. This course will cover the mathematics which will underpin the material science you will learn this year, and in future years. As well as learning the fundamentals you will gain experience at applying mathematics to physical problems.

### Lecture Content

#### Mathematics for Materials Science I

- Ordinary and Partial Differentiation (7 Lectures)
- Vectors & Matrices (12 lectures)

#### Mathematics for Materials Science II

- Taylor Series and Limits (3 lectures)
- Integration (5 lectures)
- Complex Numbers (4 lectures)
- Ordinary Differential Equations (6 lectures)

### Background reading

1st year MS

Dr E. Liberti

Prof S.C. Benjamin

19 lectures

## **Mathematics for Material Science I**

### **Ordinary and partial differentiation (EL)**

Differentiation from 1st principles, chain rule

### **Partial Differentiation (EL)**

Total derivatives, exact differentials,

Change of variables, chain rule

Applications: Spherical and polar coordinates, thermodynamics

### **Vectors (SCB)**

Scalar Product and Vector Product.

Introduction to Vector Calculus

Applications: Reciprocal lattice, Miller indices and planes

### **Matrices (SCB)**

Inverse matrices

Determinants

Orthogonal matrices

Properties of symmetric Matrices - eigenvalues and eigenvectors

Applications: Conductivity – interpretation of principle value and directions.

1st year MS

Dr A.W. Robertson

Dr N. Ares

18 lectures

## **Mathematics for Material Science II**

### **Integration (AWR)**

Evaluation of definite integrals by substitution, partial fractions, integration by parts and reduction formulae

Multiple integrals in two and three dimensions - including polar and spherical coordinates.

Applications: areas, volumes, centroids, bending moments, Random Processes and Statistical Physics

### **Complex numbers (AWR)**

Exponential form.

Argand Diagrams

de Moivre's theorem

Solutions of Polynomial Equations.

Applications: Complex Impedance, circuits involving inductors, capacitors and resistors.

### **Taylor series and limits (NA)**

Taylor series, limits and l'Hopital's rule

Applications: Low and high temperature expansions

### **Ordinary differential equations (NA)**

First Order equations: Separable variables. Linear homogeneous equations – integrating factor as a method of solution.

Applications: Cooling, circuits

Second Order Equations: Linear homogeneous with constant coefficients. Linear inhomogeneous with constant coefficients. Method of solution via auxiliary equation and particular integral.

Applications: Resonance in electrical and mechanical systems.
